Assessment of the Risk in Pharmaceutical Facility to the Human Health Based on the Ecological Surface Quality of Bacteria in the Clean Area

Mostafa Essam Eissa*1, Ahmed Saber Nouby²

¹Microbiological quality control section head in HIKMA Pharma pharmaceutical company, Egypt. ²Microbiology laboratory analyst in HIKMA Pharma pharmaceutical company, Egypt.

Abstract

In the view of many recalls of different pharmaceutical dosage forms withdrawn from the market as reported worldwide, a continuous microbiological environmental monitoring (EM) programs for bioburden in clean area should be established to identify their potential impact on the manufactured medicinal products. One of the most important criteria of observations is the surface microbe - herein focus on bacterial ecology - cleanliness monitoring. Surfaces can be direct or indirect source of the contamination of the final medicinal products. Random surface samples using contact plates were taken aseptically from the newly established pharmaceutical plant as a part from total EM and assessment program in clean rooms for drug manufacturing. After incubation of the samples a process of isolation and identification was conducted using Gram-stain and miniaturized BBL™ Crystal[™] enteric/non- fermenter (E/NF) and Gram-positive (GP) miniaturized biochemical identification system. Data were interpreted and analyzed, showing that identified bacteria were belonging to *Staphylococcaceae*, *Bacillaceae*, *Actinomycetaceae*, *Dermacoccaceae* and Micrococcaceae contribution to more than 60% from the total samples. Only 8% of the total samples (2% Gram-positive bacilli and 6% Gram-negative rods) were not identified by the commercial identification system. However, there was different colonial morphology observed for the same identified bacteria, which are represented, by Arcanobacterium pyogenes, Bacillus circulans, B. cereus, Micrococcus lylae and Kytococcus sedentarius from different surface samples. A simple quantitative risk index was applied showing significant health risk in the manufacturing environment of some bacterial families over others in order different from their ecological distribution in the pharmaceutical facility.

Key words: Environmental monitoring; contact plates; clean room; BBL[™] Crystal[™]; quantitative risk index.

1. Introduction

Microbial contamination costs companies thousands to millions of dollars annually

through the equipment damage, production downtime, product contamination,

investigations, and energy losses. The scope of the majority of reputable companies; nowadays, is focused on understanding the sources of contaminants [1]. Clean rooms essential in aseptic are pharmaceutical and food production. Screening bacteria isolates and identifying them is part of good manufacturing practice, and will aid in finding a more effective disinfection method [2]. Monitoring the environment for microorganisms is an important control function because it is important in achieving product with compendial requirements [3]. As reported in the Journal of Scientific Pakistan and Industrial Research [4], various types of tablets, both coated and non-coated, were found to be contaminated with bacteria such as Klebsiella aerogenes, Bacillus cereus, Pseudomonas aeruginosa and Staphylococcus aureus.

According to the Center for Drug Evaluation and Research (CDER) reports to the nation on drug safety and quality, there were 401 prescriptions and 101 over-the counter (OTC) drug recalls in the fiscal year of 2005. Out of the top 10 reasons for the recalls in 2005 by the FDA microbial contamination of non sterile products was listed as number three in addition to miscellaneous current good manufacturing practices (cGMP) deviations encountered during pharmaceutical drug manufacturing. A few examples from many recalls of medicinal products from 2004 to 2008 – issued by the FDA Safety Information and Adverse Event Reporting System (AERS) - included but not limited to **Bacillus** Serratia cereus, marcescens, Corynebacterium species, Staphylococcus aureus. Pseudomonas aeruginosa, Pseudomonas fluorescens/putida and Enterobacter cloacae [5]. Even in the aseptic manufacturing industry. Sterile drug products may be contaminated via their pharmaceutical ingredients, process water, packaging components, manufacturing environment, processing equipment, and manufacturing operators [6].

The current study aimed to determine the bacterial ecological distribution profile of the clean area surfaces in the newly established pharmaceutical plant and to establish quantitative risk assessment technique to verify the quality of bacterial Bioburden that could impact drug manufacturing processes. This method would allow the determination of the sources of contamination to take control over it.

2. Materials and Methods

All the nutrient media and chemicals were purchased from OXOID (Basingstoke, Hampshire) and Sigma-Alrich (St. Louis, MO 63103), respectively. Plastic 9 mm, sterile plates were purchased from Sterilin Limited (solaar house, 19 mercers row, Cambridge, UK). Isolates were obtained from the microbiology laboratory in the quality control department after incubation in Series BD 115 Incubators with natural convection (BINDER GmbH, Im Mittleren, Ösch 5, 78532 Tuttlingen, Germany). The bacterial colonies were isolated and identified using miniaturized biochemical identification kits BBL™ Crvstal™ enteric/non -fermenter (E/NF) and Grampositive (GP) Identification System and Gram-stain reagents purchased from BD (Becton Dickinson Microbiology Systems. Cockeysville, Md.). The investigated bacteria were identified using techniques as described in the instruction manual of the manufacturer of the identification system. All media were sterilized by autoclaving in validated steam sterilizer (FEDEGARI FOB3, Fedegari Autoclavi SpA, SS 235 km 8, 27010 Albuzzano Italv). (PV) All

microbial processes were made under validated and calibrated biological safety cabinet (Jouan MSC 9 Class II A2 BioSafety Cabinet, Thermo Fisher Scientific Inc. 81 Wyman Street, Waltham, MA, USA 02451). All used media were checked for their sterility and growth promotion (GP) properties as described in [7] prior to their use. Illustrations of generated data and calculations were performed using Microsoft Office Excel 2007. Pareto charts were constructed using Minitab[®] v17.1.0. Quantitative risk assessment was constructed for selected bacterial families based on Failure Mode and Effects Analysis (FMEA) method as described by Sandle [8] but with modification. FMEA schemes vary in their approach, scoring and categorization. All approaches share in common a numerical approach to each of the following categories: i) Severity ii) Occurrence iii) Detection. Where: i) Severity (S) is the impact of the presence of specific microbes on the quality of the manufacturing processes ii) Occurrence (0) is the frequency of the presence of specific bacterial family (based on past experience) iii) Detection (D) is based on the monitoring systems in place and on how likely a contamination can be detected. Based on the ordinary risk score (RS) equation:

RS= S.O.D..... Eq. (1)

However, the above method is based on a scoring system, which is subjective in nature. In order to adopt FMEA for quantitative environmental microbiological hazard evaluation. the following modification of the equation (1) was logarithmic adopted scale for in convenience of interpretation of the risk values obtained:

 $QR = log_{10} [(C. Fr) + 1] / log_{10} (ID + 1)..... Eq. (2)$

Where:

- QR= Quantitative Risk which value increases with risk, hazard and vice versa.
- C= Total microbial count obtained from standard microbiological techniques
- +1 (Nominator) = Correction factor to accommodate situations with microbial count= zero.
- Fr= Frequency of detection as a fraction from total surface samples.
- ID= Minimum Infective Dose of specific representative bacteria of the family.
- +1 (Denominator) = Correction factor to accommodate those microorganisms with ID= 1.

By analogy, the nominator represented the frequency (0) and $(1 / \log_{10} (\text{ID} + 1))$ as the severity (S). Detectability factor was omitted in the last equation because it has no variable influence in the current study. During the initial phase of microbiological environmental monitoring (EM), there is not sufficient amount of data to allow trending and to generate control charts for the total microbial count (C) with control limit (CL) and an upper control limit (UCL). So the value taken would be the action limit of the area class C to calculate the risk at its maximum value of C= 25 CFU/25 cm^2 for each bacterial family [9]. It should be noted that the risk value should be monitored to the microbiological hazard that could be transferred patient through to pharmaceutical product. However, direct measurement through incorporation of the product parameters would be hard to accomplish because it is difficult to calculate the transfer rate or factor from surface to drug unless extensive, prolonged study could be performed to correlate surface to medicinal product contamination and its route and mechanism which must be

specific for each area, product and process combination.

3. Results and Discussion

Table 1, 2 and 3 shows the identified bacteria, their families, colonial morphologies, biochemical reactions (required by the miniaturized biochemical identification system for E/NF and GP kits) and their possible source. Bacteria from families *Staphylococcaceae*, *Bacillaceae*, *Actinomycetaceae*, *Dermacoccaceae* and *Micrococcaceae* contributed to about 64% of the total samples. This finding is illustrated by Pareto chart in Figure 1.

Table 1. Identified Gram-Negative ba	cilli, their families,	colonial morphologies,	biochemical
tests and p	profiles and commo	n sources.	

Family	Microorganism	Colonial Morphology	Oxidase /Indole	Possible Source*	
Moraxella- ceae	Acinetobacter lwoffii	Moderate to large, wrinkled and white	N/N	Soil, Water, Human	
Enterobac- teriaceae	Klebsiella pneumoniae ssp. Ozaenae**	Small to moderate, round, entire, raised and transparent	N/N	Soil, Human,	
	Klebsiella pneumoniae ssp. rhinosclerometis	Large, round, entire, convex and white	N/N	Allilla	
NA	Gram-Negative Rods	Small, round, entire and transparent	N/N		
		Large, round, entire, raised and translucent buff	N/N	NA	
		Small, round, entire, flat and buff	N/N		
Pseudomon- adaceae	Pseudomonas putida	Large, entire, convex and creamy	P/N	Soil, Water	
Sphingomo- nadaceae	Sphingomonas paucimobilis	Large, irregular, smooth, flat and reddish orange	N/N	Soil, Water, Plant	

*= Information on microorganisms was available from the database of the identification software and/or its literatures.

**= Identification system gave an alternative ID of a slightly lower value of confidence factor (c.f.) to *Serratia fonticola* which is similar to *Klebsiella pneumoniae* in habitat and belongs to the same family. N= Negative result. P= Positive result.

If unidentified microorganisms were excluded, Gram-positive organisms would be contributed by 84% (cocci 52% and bacilli 32%) from the total detected bacteria on surfaces while Gram-negative rods gave 16% of the total samples. Bacteria widely distributed in clean rooms are mainly a group of Gram positive strains, showing high resistance to selected disinfectants as demonstrated by Wu and Liu [2]. Their study also showed that predominant contaminant bacteria in the clean rooms of pharmaceutical facility were a group of Gram positive bacteria: either spore-forming *Bacillus species* or non-sporulating *Staphylococcus species* and *Microbacterium species*. This is demonstrated in Figure 2 which shows that human, soil and water sources of contaminations on surfaces contributed by 43%, 32% and 25%, respectively, which is based on the possible sources of contamination from Tables 1, 2 and 3. Most gram-positive bacteria, such as *Enterococcus spp.* (including VRE), *Staphylococcus aureus* (including MRSA), or *Streptococcus pyogenes*, survive for months on dry surfaces. Many gramnegative species, such as *Acinetobacter spp., Escherichia coli, Klebsiella spp., Pseudomonas aeruginosa, Serratia marcescens*, or *Shigella spp.*, can also survive for months [10].

Table 2. Identified Gram-Positive cocci, their families, colonial morphologies, biochemical
tests and profiles and common sources.

Family	Microorganism	Colonial Morphology	Possible Source*	
Enterococcaceae	Enterococcus	Moderate, round, convex and	Soil Water	
	faecium	translucent	Human, Animal, Food	
	Enterococcus	Small, round, raised, entire and		
	solitarius	colorless		
		Small, round, entire, convex and		
		white		
	Kutococcus	Small, round, entire, raised and white		
Dermacoccaceae	sodontarius	Small, irregular, smooth, convex,	Water, Human	
	seuenturius	mucoid and yellowish white		
		Small, round, smooth, convex and		
		white		
	Micrococcus	Small, round, smooth, convex and	Wido distribution	
	luteus	yellow	in nature, Soil, Dust, Water, Air	
Micrococcaceae	Micrococcus	Small, round, smooth, convex and		
		buff		
	lylue	Round, entire, convex and orange	Human, Manimais	
Lactobacillaceae	Pediococcus	Characteristic odor, small, round,	Human, Animal,	
Luciobucinuceue	spp.	smooth, convex and buff	Plant, Food	
	Staphylococcus	Small, round, smooth, convex and	Human	
	aureus	orange	ITulliali	
ae	Staphylococcus	Small, round, smooth, convex and	Human, Animal	
ал	capitis	white		
CCC	Stanbulococcus	Small, round, entire, convex, smooth	Human	
000	anidarmidis	and white		
aphyld	epidermidis	Small, round, entire, raised and white		
	Staphylococcus	Small to moderate, round, convex,	Human Animal	
St	heamolyticus	entire and white		
	Staphylococcus	Small to Moderate, round, entire,	numan, Ammai	
	hominis	convex and white		
Strontococcacocc	Streptococcus	Small, round, smooth, convex and	Uuman	
Streptococcaceae	sanguinis	white	Human	

*= Information on microorganisms was available from the database of the identification software and/or its literatures.

Table 3. Identified Gram-Positive bacilli, their families, colonial morphologies
biochemical tests and profiles and common sources.

Family	Microorganism	Colonial Morphology	Possible Source*	
Actinomycetaceae	Arcanobacterium pyogenes	Round, smooth, flat and buff with translucent halos Small, round, smooth, convex and pale yellow Large wayy, raised and wrinkled	Human, Animal	
	Rothia dentocariosa	Moderate to large, wavy, flat and white	Human	
	Bacillus cereus	Large, round, entire, convex and white	Soil, Food, Environment, Insects	
	Bacillus circulans	Small, round, rough, flat and buff Large, round, raised and white	Soil	
Bacillaceae	Bacillus licheniformis	Large, irregular, lobate, raised and gray	Soil, Birds	
	Bacillus pumilus	Moderate, irregular, wrinkled, raised and white Moderate, round, wrinkled, raised and creamy Medium, irregular, rough, flat and buff Large, wavy, crescent and wrinkled and buff	Soil	
	Bacillus subtilis	Moderate to large, round, wrinkled and convex	Soil, Water	
Corynebacteriaceae	Corynobacterium pseudotuberculosis	Round, smooth, convex, entire and creamy white	Soil, Water, Plants, Food products, Human, Animals	
Bifidobacteriaceae	Gardnerella vaginalis	Filamentous, irregular, raised and white	Human	
NA	Gram-Positive Bacilli	Small,round, entire, flat and colorless	NA	
Microbacteriaceae	Leifsonia aquaticum	Fine, round, flat, entire and light buff	Water	
Cellulomonadaceae	Oerskovia spp.	Large, round, entire, convex and light vellow	Soil, Water	

*= Information on microorganisms was available from the database of the identification software and/or its literatures.

In the study of Mostafa, 2014, the environmental monitoring results showed that *Staphylococcus species* were the predominant microorganism isolated (38.4% of total positive samples) followed by *Bacillus species* (25.8% of total positive samples) then *Micrococcus* species (22.4%) [11].

Figure 1. Pareto chart showing the relative abundance of bacterial families among selected surface samples taken from the clean area in non-sterile pharmaceutical manufacturing facility showing that *Staphylococcaceae*, *Bacillaceae*, *Actinomycetaceae* and *Dermacoccaceae* contributed by more than 57% from the total samples. (The plot was generated using Minitab® v17.1.0)

4 shows data required Table for calculation of QR on the manufacturing processes of the medicinal products and the obtained QR values for each bacterial family with the exclusion of those with no data for ID. In order to assess major contributors on the risk factor, Pareto diagram was constructed as illustrated in Figure 3. Interestingly, QR showed a different order of the risk prioritization from that of the ecological distribution of bacteria on surfaces in the clean area with Enterobacteriaceae and Staphylococcaceae contribution above 50% from the total risk.

This is based on the primary selection of ID route by ingestion. Table 1 shows that the colonial morphology of the same bacterial species varied and this is evident with Bacillus circulans and Bacillus pumilus and in Table 2 with Micrococcus lylae. This may indicate that identification of bacteria based on colony morphology alone may be inadequate and must be supplemented with other supportive techniques such as biochemical tests and microscopical examination. This is not surprising, in the view of that characteristic defined by a colony's morphology may be used at a superficial level to distinguish between types of microorganisms. For example, there are differences in morphologies when rough and smooth colonies of the same bacterial species are examined. Another comparison can be made when describing pigmented colonies [12].

Figure 2. 3-D Stacked Bar diagram showing the contribution of each type of bacteria from each of the major sources of the contamination in the clean rooms based on the frequency of detection from surface samples. (The graph was generated using Microsoft Office Excel 2007).

Figure 3. Pareto chart showing the QR of medicinally significant bacterial families among selected surface samples taken from the clean area in non-sterile pharmaceutical manufacturing and testing facilities showing that *Enterobacteriaceae, Staphylococcaceae* and *Bacillaceae* contributed by more than 65% from the total calculated risk. (The plot was generated using Minitab® v17.1.0)

An initial extensive identification program of EM isolates was an essential step as the most likely microflora found in pharmaceutical manufacturing can be hard to come by a definite source. The most commonly occurring microorganisms come from human skin (either commensurable or transient) are Gram-positive microorganisms which include the following: *Staphylococcus aureus, Micrococcus species* and *Bacillus species.* Whereas those associated with eyes, ears and mucus include Gramnegative microorganisms, which can arise on rare occasions directly from the operator and include *Pseudomonas aeruginosa* [13]. Strains of *Staphylococcus* *aureus,* members of *Enterobacteriaceae* and *Pseudomonas aeruginosa* were isolated from pharmaceutical effluent water [14].

 Table 4. QR calculated for medically significant bacterial families, excluding those unidentified and non-clinically significant bacteria.

Ŀ	Bacterial Family	Relative	Infective Dose*	QR
S		Abundance	[15,16,17,18,19]	
1	Actinomycetaceae	0.09	5.6x10 ⁹ (Oth.)	0.051
2	Bacillaceae	0.19	1.0x10 ⁶ (Ing.), 2.0x10 ⁴ (Skn.), 8.0x10 ³ (Inh.)	0.127
3	Bifidobacteriaceae	0.02	2.0x10 ¹⁰ (Oth.)	0.018
4	Corynebacteriaceae	0.02	3.6x10 ⁷ (Oth.)	0.025
5	Enterobacteriaceae	0.04	1.0x10 ¹ (Ing.)	0.302
6	Enterococcaceae	0.04	1.0x10 ⁷ (Ing.)	0.045
7	Microbacteriaceae**	0.02	3.6x10 ⁷ (Oth.)	0.025
8	Moraxellaceae	0.02	1.0x10 ⁶ (Oth.)	0.031
9	Pseudomonadaceae	0.02	1.0x10 ³ (Skn), 1.0x10 ¹⁰ (Ing.)	0.062
10	Sphingomonadaceae	0.02	1.0x10 ⁶ (Ing.)	0.031
11	Staphylococcaceae	0.21	1.0x10 ⁵ (Oth.)	0.160
12	Streptococcaceae	0.02	1.0x10 ³ (Ing.)	0.062

*= In the absence of data on the infective doses (ID) of the human, those of the experimental animals were used till reliable data on the infectious doses of man could be determined. The lowest ID value was chosen if literatures provide a range of values.

**= *L. aquaticum* was originally classified as *'Corynebacterium aquaticum'* on the basis of its morphological and physiological characteristics [20], so the approach of giving the same ID of *Corynebacteriaceae* to *Microbacteriaceae* was selected.

N.B. For those microorganisms with ID for more than one route of administration, ID per ingestion route (Ing.) was chosen primarily over skin (Skn.) and inhalation (Inh.) route. Bacteria with ID value per other (Oth.) routes of infection was used where no other data were available for the infective dose per oral route.

The current risk highlights the importance of covering the gap between the increasing number of pathogenic microorganisms and the available data about their infectiveness properties and its doses. The FDA Center for Food Safety and Applied Nutrition (CFSAN) has published a handbook on food-borne pathogenic bacteria referred to as the "Bad Bug Book". Listed in this handbook is the following known pathogenic, bacteria, including: Salmonella spp., Staphylococcus aureus, Yersinia enterocolitica, Yersinia pseudotuberculosis, Shigella spp., Streptococcus spp. Bacillus spp., Enterococcus spp., Klebsiella pneumoniae, Pseudomonas spp., Serratia marcescens Staphylococcus and epidermidis Microbiology laboratory analyst in HIKMA Pharma pharmaceutical company, Egypt. It seems that with the increase in the number of people with weak immune systems and microorganisms that have developed resistance to antimicrobials, the list of organisms of concern continues to grow. Therefore, it behooves the pharmaceutical microbiologist to stay abreast of the latest publications on the topic of objectionable organisms, to include published product recalls listed in trade publications such as The Gold Sheet [5].

The QR applied herein showed agreement with that required by USP<62>, 2014 with the exception of that Bacillaceae was ranked at the 3rd highest priority in the hazard of the product, while it is not listed by Pharmacopeia in the test of specified microorganisms [22]. This is not strange in view of what is listed in the "Bad Bug Book". On the other hand. Pseudomonadaceae - in the present study - ranked 11th in the tested bacterial families when the oral route is considered which indicated that it is of low risk priority when considering manufacturing oral products. This is in agreement with Martinez, 2002 conclusion [23]. However, when considering the dermal route the risk significantly increased, indicating a rise in the possible hazard that could be delivered to patients through skin.

Conclusion

The current applied methodology for assessment and control of the microbiological surface cleanliness in the clean rooms in the non-sterile pharmaceutical manufacturing provides a guide for improvement and minimization of microbial hazard delivered to the customers through medicinal products in order to provide safe drug to the patients. This risk may work in complementation with similar risk studies performed for air, pharmaceutical water and other inputs that influence the quality of the manufactured products. When sufficient data are generated from an EM program of the clean area, the risk, study can be further broken into specific parts of each product, process and area. The limitations of the current OR are affected bv inadequacy of data about infective doses for each microorganism and the difficulty of calculating of the transfer factor of contamination from surface to the product either directly or indirectly. The current procedure of QR can be used as a milestone for microbiological risk control in other industries and fields that affect customer health such as food, cosmetics, hospitals and other healthcare facilities.
